

1 Design

There is a picture basically can describe my description. The method I chose is to design an inode which includes basically file control block implementation and 13 direct access pointer, 1 single indirect pointer, 1 double indirect pointer, and one triple indirect pointer.

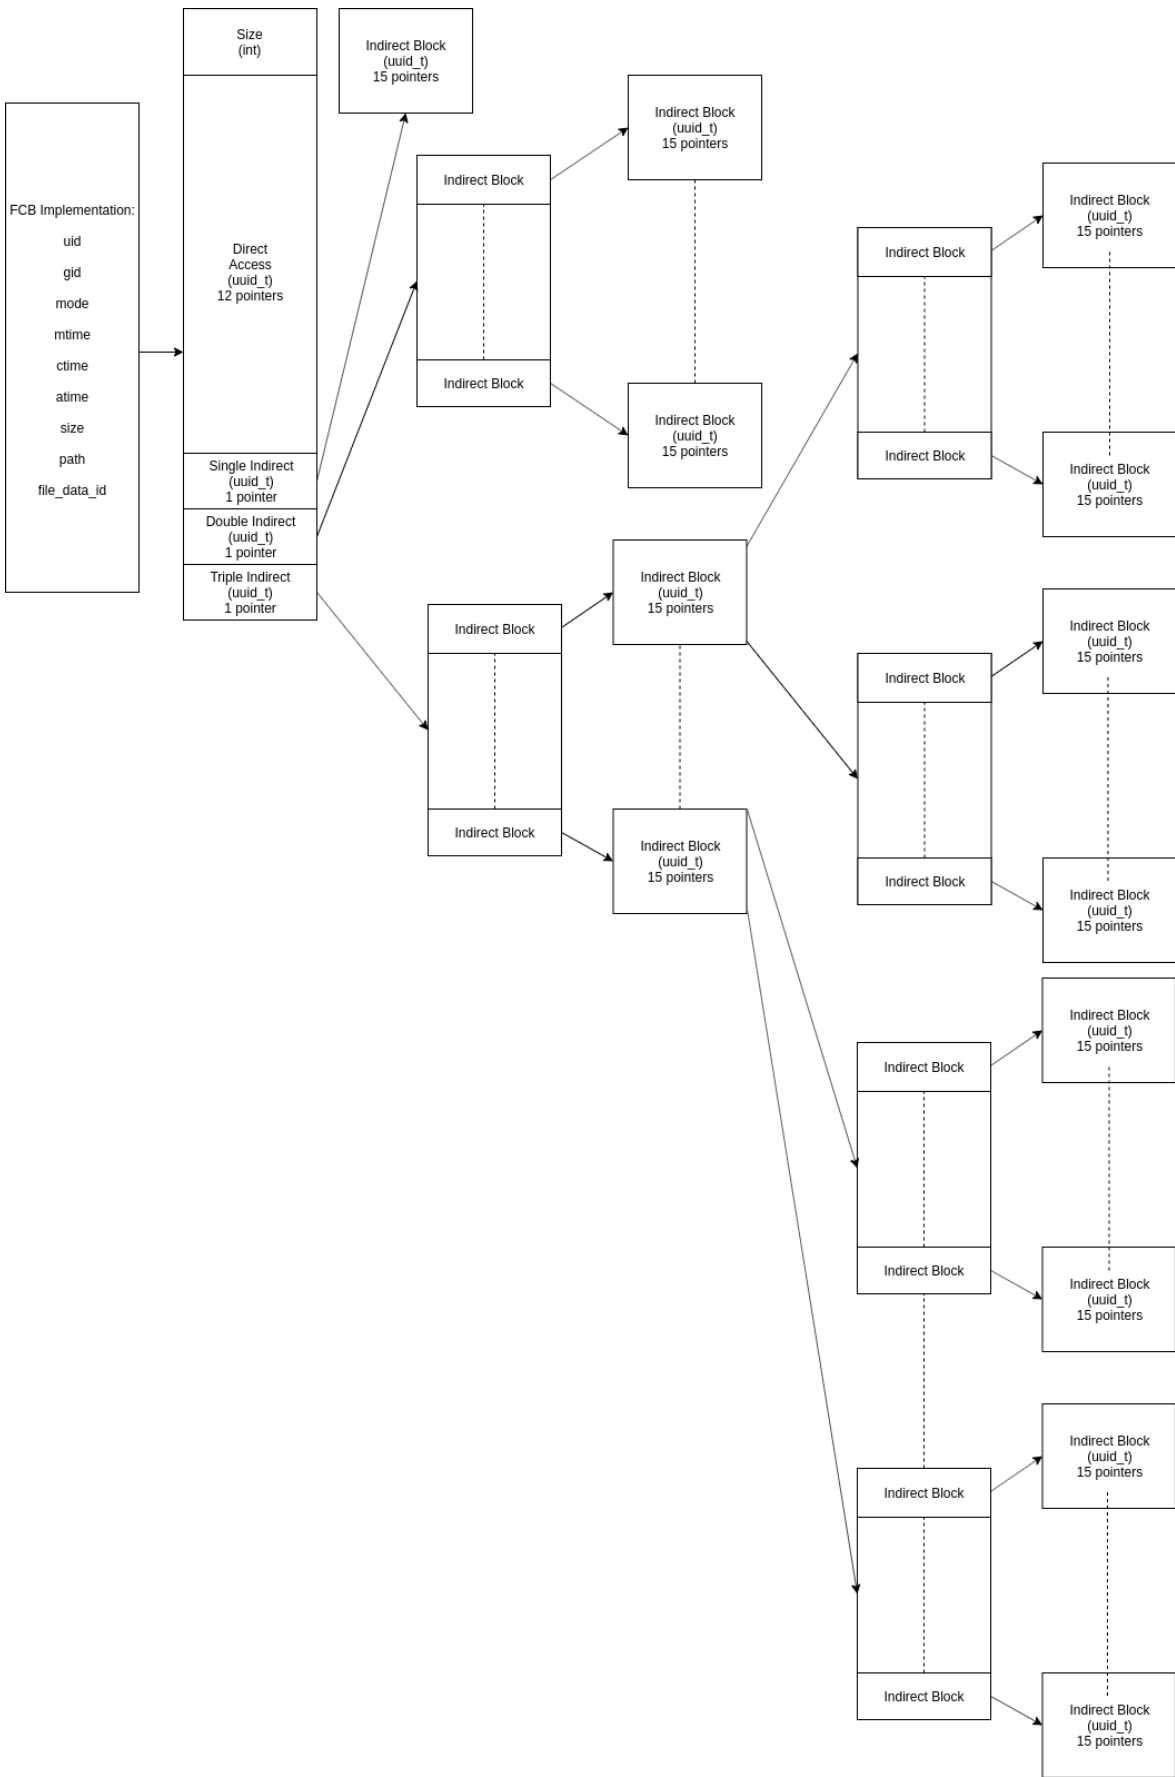

Figure 1: Inode full design

There is a root inode in the memory with a simple and understandable key that can access the inode. For an arbitrary length file path and smaller memory use, we created a structure which mainly contains the key of the fcb and the name of the file. This structure can be called entry, which is the entry of the fcb.

For directories, entries will connect to the direct access pointer first. Only when the direct access pointer used up, it will generate a UUID and connect to the indirect pointers. Each indirect block

has 15 pointers for connecting to different access blocks. So the single indirect entries will allow 15 entries, double indirect entries allow 15^{15} entries and triple indirect entries allow $15^{15^{15}}$ entries, which is actually big enough for storing all kinds of things.

Detailed design is shown as follows:

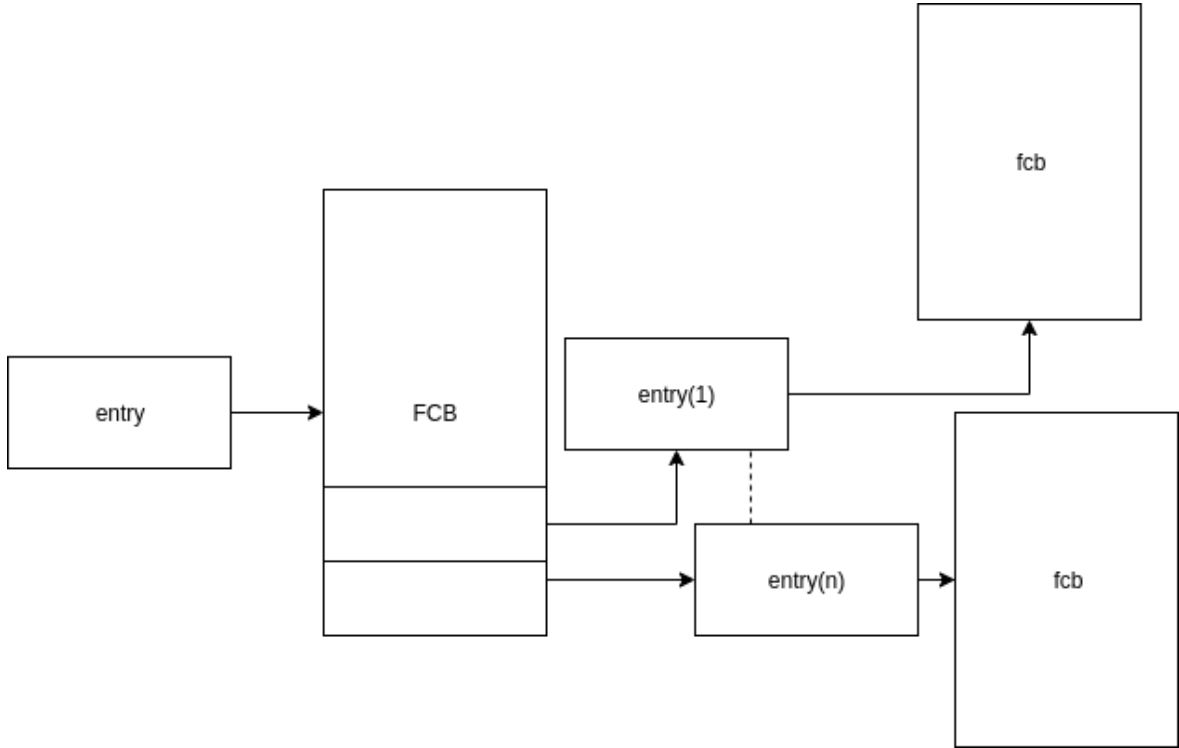

Figure 2: design

FCB only pay response to other entries but does not care about any other fcb. In a contract, entries only pay response to its FCB but do not pay attention to another entries. This makes finding a specific file much easier and make the file structure more clear, as each entry has a single pathname and a single UUID key, which has an obvious advantage on implementing a file system.

2 Implementation

In this section, I will take an example path to explain the implementation: `/a/aa/aaaa.txt`

get attribute

This function will judge whether it is root file first, then if not it will directly access the fcb of the path and retrieve the information of such block.

access to the path from local argument

This can be finished by using `strtok(str, "/")`, each `strtok` will change one `/` to `\0` and return the pointer to the string, which is a terminate of the string. This allows hierarchy access and to the next file control block. An example of this is when we use `strtok` to solve the path, we will get `a` the first time, then we got `aa` and so on.

splitting path name and dir name

This can be done by using `strrchr()`, which allows programmers to find last delimit and return the pointer of such delimit. Then I replaced the pointer to `\0` and the path starts with starting pointer and the file name is the value of `pointer + 1`

create file and directories

These two functions can be done just the same, we will access to the path by using splitting function and access function, then the program will find a space to generate a new UUID and then call the create function and write back new fcb and old fcb.

find specific fcb using name

When we access the directory fcb, we will fetch entries with for loop and use `strcmp()` to compare names stored in the entrance node with the filename given. If the filename is the same as the pathname, it will return 0 and a passing pointer to fcb and entrance node in the local argument.

deletion

When we want to delete a file, the program will access the path first, such as when deleting *aaaa.txt*, the program will access */a/aa*. Then the program will access the fcb and swipe data in direct access blocks, and then delete data from unqlite. Then it will delete the entrance node and fcb node from the unqlite and clear the key in the fcb of the path. Then write back will happen and deletion has completed.

free space generator

When we are making directories or writing files, we will need free space for storing the file or directory UUID. A generator will read through direct access and then find a zero UUID. Then the program will generate this UUID and write back the data block. Such UUID will be passed outside the function for storing the data block.

modular

It is quite complex and lots of duplicates when trying to fetch and store the data block. So I make things modular such as to define functions of reading and fetching, which actually prevented lots of duplicates.

writing to the file

Writing to the file will create a file structure first, then create the entry fcb pair if it does not exist. The file structure will link to the first fcb direct access and the fcb should be write back with modification.

3 Testing

chmod and chown(Figure 3)

Chmod and Chown will change the accessible protection mode of the file.

```
hl74@pc7-038-l:~/mnt $ chmod 777 b
hl74@pc7-038-l:~/mnt $ chown root b
hl74@pc7-038-l:~/mnt $ ls -la
total 17
drw-rw-r-- 304 hl74 hl74      0 Nov 19 00:06 ./
drwx--x--x  70 hl74 hl74     93 Nov 19 00:02 ../
-rwxrwxrwx   0 root nobody 304 Nov 19 00:48 b*
```

Figure 3: chmod and chown

hierarchy system(Figure 4)

Hierarchy system will shows the system with tree structure

```

hl74@pc7-038-l:~/mnt $ ls -la
total 17
drw-rw-r-- 304 hl74 hl74  0 Nov 19 00:06 ./
drwx--x--x  70 hl74 hl74 93 Nov 19 00:02 ../
hl74@pc7-038-l:~/mnt $ mkdir newdir
hl74@pc7-038-l:~/mnt $ cd newdir/
hl74@pc7-038-l:~/mnt/newdir $ mkdir adir
hl74@pc7-038-l:~/mnt/newdir $ cd adir/
hl74@pc7-038-l:~/mnt/newdir/adir $ mkdir sdir
hl74@pc7-038-l:~/mnt/newdir/adir $ cd sdir
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ ls -la
total 0
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 ./
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 ../
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ mkdir a
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ mkdir b
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ mkdir c
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ mkdir d
hl74@pc7-038-l:~/mnt/newdir/adir/sdir $ ls -la
total 0
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 ./
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 ../
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 a/
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 b/
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 c/
drwxrwxr-x 0 hl74 hl74 304 Jan  1 1970 d/

```

Figure 4: make directory inside another directory

utime(Figure 5)

utime allows to change modification time for file.

```

hl74@pc7-038-l:~/mnt $ touch -t 201202021111 b
touch: cannot touch 'b': Permission denied
hl74@pc7-038-l:~/mnt $ touch -t 201202021111 c
hl74@pc7-038-l:~/mnt $ stat c
  File: c
  Size: 304          Blocks: 0          IO Block: 4096   regular file

```

Figure 5: chmod and chown

remove directory and remove file(Figure 6)

rmdir and rm allows user to remove the directory and remove the file

```
hl74@pc7-038-l:~/mnt $ ls -la
total 17
drw-rw-r-- 304 hl74 hl74  0 Nov 19 00:06 ./
drwx--x--x  70 hl74 hl74 93 Nov 19 00:02 ../
-rw-rw-r--   0 hl74 hl74 304 Nov 19 00:48 a
-rw-rw-r--   0 hl74 hl74 304 Nov 19 00:48 b
drwxrwxr-x   0 hl74 hl74 304 Jan  1 1970 newdir/
hl74@pc7-038-l:~/mnt $ rm a
hl74@pc7-038-l:~/mnt $ rmdir newdir/
hl74@pc7-038-l:~/mnt $ ls -la
total 17
drw-rw-r-- 304 hl74 hl74  0 Nov 19 00:06 ./
drwx--x--x  70 hl74 hl74 93 Nov 19 00:02 ../
-rw-rw-r--   0 hl74 hl74 304 Nov 19 00:48 b
```

Figure 6: remove

Writing to a file(Figure 7)

using cat in a terminal allows users to read the file data. Using `>` allows user to write into data with pipe.

```
hl74@pc7-038-l:~/mnt $ echo "a" >a.txt
hl74@pc7-038-l:~/mnt $ cat a.txt
a
hl74@pc7-038-l:~/mnt $ echo "aaaaaaaaaa" >a.txt
hl74@pc7-038-l:~/mnt $ cat a.txt
aaaaaaaaaa
hl74@pc7-038-l:~/mnt $
```

Figure 7: read and write

4 Summary

Several functions has not implemented and there are still lots of bugs available. I am currently in my lowest expect for my final grades and feels quite upset.

This Practical is so hard and time is not generally enough for finishing all of it. I am sad about not finishing the whole implementation and leave a program full of bugs. But I actually work for 40+ hours without any sleep, just my brain has stopped running and I am so tired to think of anything. The only thing I can do is to finish the report and show my design and implementations I have finished. I am so sorry about that.
